Center for Computational Natural Sciences and Bioinformatics (CCNSB)

International Institute of Information Technology, Hyderabad

## Introduction

➤ The backbone conformation of amino acids in proteins is represented mainly by two torsion angles;  $\phi$  and  $\psi$ . Ramachandran map is a way to visualize these torsion angles in protein structures.

➤ Here we analyze the nature and distribution of disallowed and allowed/disallowed Ramachandran conformations of amino acids observed in protein structures.

## Material & Method

## Analysis of Conformational Propensities in Disallowed & Allowed regions

Fig-2: Conformational propensity of 78,213 non-Gly residues (Ramachandran Plot)

Fig-3: Showing Clustering in the disallowed region of Ramachandran Plot

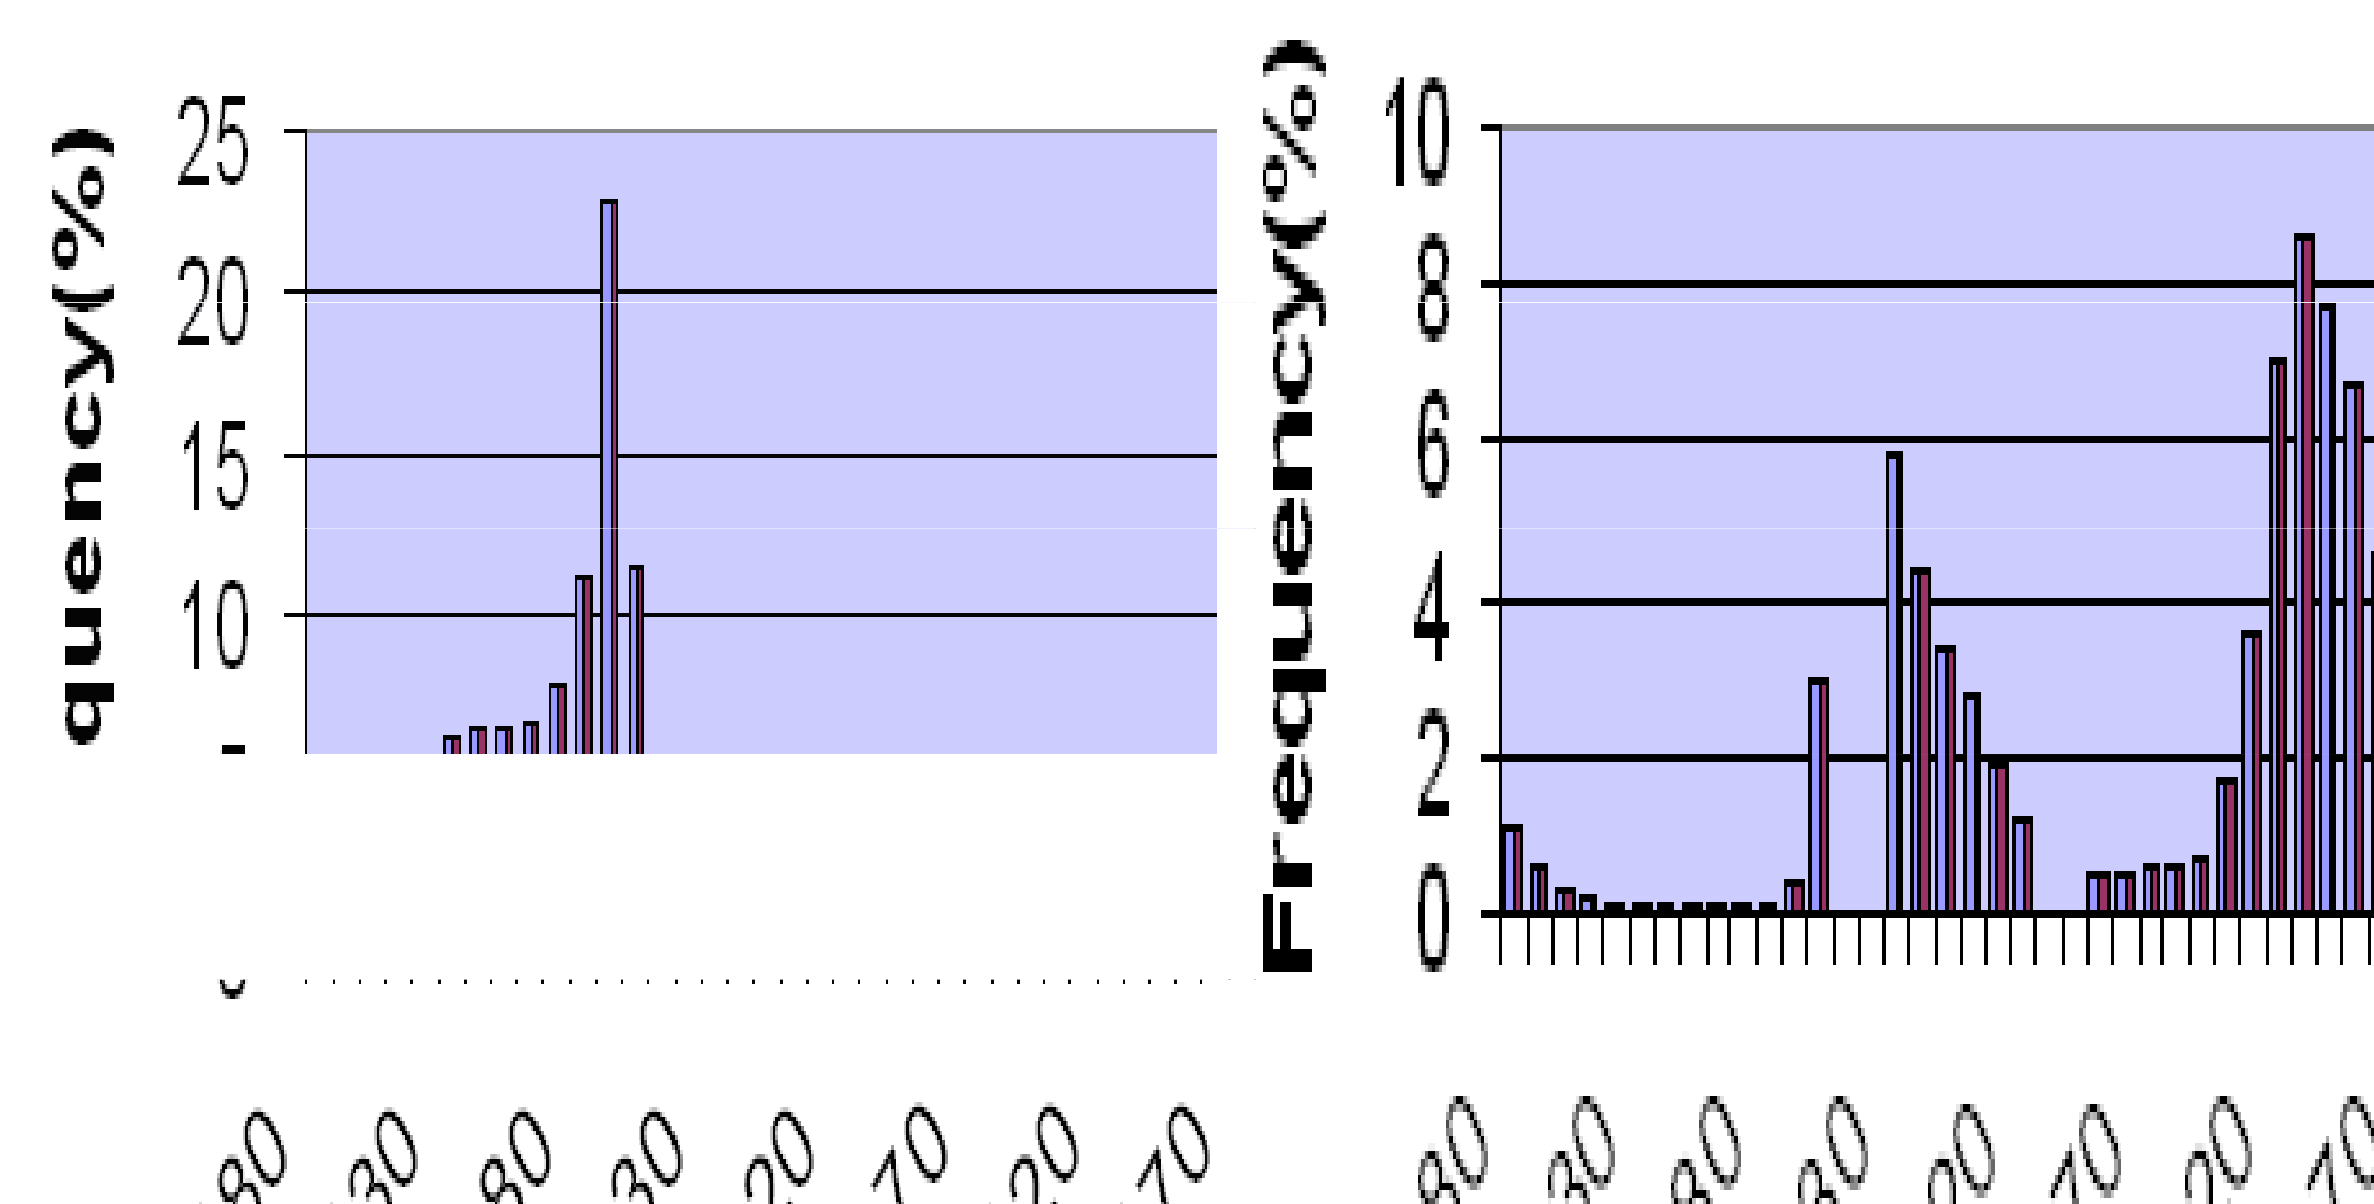

Fig -4: Distribution of  $\phi$  &  $\psi$  angle in the allowed region

## Conclusion

- Very small fraction of residues (~0.4 %) lie in appreciably disallowed regions
- Small polar/charged residues Asn, Asp, Ser, Thr showed greater probability of adopting unusual backbone.
- The bulky charged residues Glu, Lys, Gln and Arg have a relatively low propensity for backbone distortions.
- Bulky hydrophobic residues, found predominantly in well packed interiors of proteins like Ile, Val and other aromatic amino acids like Phe, Trp and Tyr do not generally adopt disallowed conformation
- In the allowed region irrespective of the type of amino acid except Gly:

For  $\phi$ : { -70,-60}  
For  $\psi$ : {140:150}

## Analysis

	8	7	2	1	2	0	26
ATA							
SER	10	8	3	1	14	4	40
